Module 1 Cheat Sheet: Python Basics

Package/Method	Description	Code Example
Comments	Comments are lines of text that are ignored by the Python interpreter when executing	 1. 1 1. # This is a comment
	the code<./td>	Copied! Syntax: 1. 1
Concatenation	Combines (concatenates) strings.	<pre>1. concatenated_string = string1 + string2 Copied!</pre>
		Example: 1. 1
		<pre>1. result = "Hello" + " John"</pre> <pre>Copied!</pre>
		Example:
		2. 2 3. 3 4. 4 5. 5 6. 6 7. 7 8. 8 9. 9 10. 10
Data Types	- Integer - Float - Boolean - String	 x=7 # Integer Value y=12.4 # Float Value is_valid = True # Boolean Value is_valid = False # Boolean Value F_Name = "John" # String Value
		Copied! Example: 1. 1 2. 2
Indexing	Accesses character at a specific index.	1. my_string="Hello" 2. char = my_string[0] Copied!
		Syntax: 1. 1 1. len(string_name)
		Copied!
len()	Returns the length of a string.	Example: 1. 1
		 2. 2 my_string="Hello" length = len(my_string)
		Copied! Example:
lower()	Converts string to lowercase.	1. 1 2. 2
		<pre>1. my_string="Hello" 2. uppercase_text = my_string.lower() Copied!</pre>
print()	Prints the message or variable inside `()`.	Example:
		 1. 1 2. 2 1. print("Hello, world")
		2. print(a+b)

```
Example:
                                                                                                                                     2. 2
                                                                                                                                    3. 3
4. 4
5. 5
                         - Addition (+): Adds two values together.
                                                                                                                                     6. 6
7. 7
                         - Subtraction (-): Subtracts one value from another.
                         - Multiplication (*): Multiplies two values.
Python Operators
                         - Division (/): Divides one value by another, returns a float.
                                                                                                                                     1. x = 9 y = 4
2. result_add= x + y \# Addition
                         - Floor Division (//): Divides one value by another, returns the quotient as an integer.
                                                                                                                                    2. result_sub= x - y # AddItion
3. result_sub= x - y # Subtraction
4. result_mul= x * y # Multiplication
5. result_div= x / y # Division
6. result_fdiv= x // y # Floor Division
7. result_mod= x % y # Modulo
                         - Modulo (%): Returns the remainder after division.
                                                                                                                                  Copied!
                                                                                                                                 Example:
                                                                                                                                     1. 1
replace()
                         Replaces substrings.
                                                                                                                                     1. my_string="Hello"
2. new_text = my_string.replace("Hello", "Hi")
                                                                                                                                 Copied!
                                                                                                                                 Syntax:
                                                                                                                                     1. substring = string_name[start:end]
                                                                                                                                 Copied!
Slicing
                         Extracts a portion of the string.
                                                                                                                                 Example:
                                                                                                                                     1. 1
                                                                                                                                     1. my_string="Hello" substring = my_string[0:5]
                                                                                                                                  Copied!
                                                                                                                                 Example:
                                                                                                                                     1. 1
2. 2
split()
                         Splits string into a list based on a delimiter.
                                                                                                                                     1. my_string="Hello"
2. split_text = my_string.split(",")
                                                                                                                                 Copied!
                                                                                                                                 Example:
                                                                                                                                     1. 1
strip()
                         Removes leading/trailing whitespace.
                                                                                                                                     1. my_string="Hello"
2. trimmed = my_string.strip()
                                                                                                                                 Copied!
                                                                                                                                 Example:
upper()
                         Converts string to uppercase.

    my_string="Hello"

                                                                                                                                     2. uppercase_text = my_string.upper()
                                                                                                                                 Copied!
                                                                                                                                 Syntax:
                                                                                                                                     1. variable_name = value
                                                                                                                                 Copied!
Variable
                         Assigns a value to a variable.
                                                                                                                                 Example:
Assignment
                                                                                                                                     2. 2
                                                                                                                                     1. name="John" # assigning John to variable name 2. x = 5 # assigning 5 to variable x
                                                                                                                                  Copied!
```
